1 Abstract

Personal finance systems exist in abundance nowadays, from open source to proprietary ones. They all tend to revolve around a basic common theme: providing accurate information about an individual's income and expenditure. Beyond this, they tend to vary in which features are implemented. The system designed and built for this project focuses on the use of the bookkeeping principle of double entry and the concept of pattern matching to find effective ways to categorise a user's expenditure, and provide them with relevant financial information to assist in decision making.

2 Introduction

Vaasen et al. (2009 cited Boczko, 2012, p. 8) suggests that an accounting information system's main purpose is to provide information to internal and external stakeholders. Although this refers to accounting systems for business, it could be argued that the same concept could be applied for personal finance systems – except that, in this case, the main stakeholder would be the individual using the system (that is, the user). In fact, one of the most widely known accounting systems available in the market, Quicken™, was conceived around the idea that there should be more efficient and less tedious ways to organise one's personal financial information than doing it manually (Quicken Inc., 2017). This project has been developed based on these ideas.

The system has been developed using the principle of *double entry bookkeeping*, which states that every transaction should affect two accounts, one being credited (Out) and one debited (In). An account, for the scope of this project, either refers to a category created by the user, or to the user's *cash book* – the contents of their bank account plus any manual entry which they make. In bookkeeping, each account can be classified as an *asset*, *liability*, *income* or *expenditure*. Whether the account increases or decreases will depend on which of these categories it falls under: *debits* will increase *assets* and *expense* accounts, and *credits* will increase *liability*, *capital* or *income* accounts (Wood et al., 2004, pp. 18-19).

This report documents the work of the project. Each chapter delineates a specific aspect of the development lifecycle, which is in line with the development process listed in 3. Chapter 4 identifies the identified requirements which were used as motivation for the system to be developed.

Analysis of requirements has been incorporated in the design section (Chapter 5). This is also where the first mention of patterns can be seen.

3 Development Method

For this project, an approach similar to that adopted by Bennett et al. (2010, p. 77) regarding methodology has been employed, where no specific named methodology is espoused, but concepts of object-oriented analysis and design were applied, in an iterative and incremental fashion, using UML. More details about which concepts were used and the methodologies which originated them can be found in the following subsections.

3.1 The use of Universal Modelling Language (UML) constructs

UML is a modelling language created with the intention of providing system architects, software engineers and developers with a common set of modelling tools, with a defined syntax, which would help them better analyse and design software-based systems, and to model business and similar processes (OMG, 2015, p. 43). It defines several constructs which have been employed throughout this report in order to model the specifications of the system, such as:

Use Case diagrams As a useful, high level tool to document users' requirements (Bennett et al., 2010, p. 138), use case diagrams have been used to develop the requirements model of the system.

Activity diagrams

Class diagrams

Sequence diagrams

3.2 Requirements Capture Methods

Due to the nature of the system being for personal rather than commercial use – that is, by individuals rather than business entities – the usual fact finding techniques do not apply specifically well. However, the closest match identified to the techniques utilised has been with '*Knowledge Acquisition*'. This relates to the process of capturing knowledge from an expert (Bennett et al., 2010, p. 150). In this particular case, though perhaps not qualifying as an expert, the author's qualification and experience in accounting and bookkeeping was used to capture the main requirements.

3.3 Analysis and Design patterns

Where appropriate, analysis and design patterns will be used, either in full or with some modifications.

Fowler (1997, Section 1.3) defines a pattern as “an idea that has been useful in one context and will probably be useful in others”. This project will therefore attempt to utilise patterns where appropriate in order to prove this concept, and as an attempt to make use of the experience already acquired in the domain (or domains) in question.

The concept of *domain* here is being used, as defined by Evans (2004, p. 2), as the “activity or interest of its user” – the “subject area to which the user applies the program”.

Analysis patterns will be used “when trying to understand the problem” domain (Fowler, 1997, Section 1.1).

4 Requirements

This project is building a system to find a solution for a problem. One of the first steps in order to do this is to try to understand what the problem is – that is, try to map the requirements of the software. Bennett et al. (2010, pp. 140-142) categorises requirements as being of three types:

Functional Requirements The system’s functionality – what it is expected to do.

Non-functional Requirements How well the system delivers its functionality. These requirements are related to the performance, scalability, availability, recovery time, security, and others.

Usability Requirements These relate to how effectively, efficiently and satisfactorily users can achieve their goals in the existing system. User interfaces can play a big part in meeting these requirements.

These definitions will be employed when trying to classify the requirements and model the problem domain. The initial iterations will be focused more on the functional and usability requirements, paying some attention as well to specific non-functional requirements such as performance and security.

4.1 Functional Requirements

Any personal accounting system should be able to provide accurate and relevant summaries of an individual’s financial status. In order to do this, the user needs to be able to supply the system with the necessary data so that it can be analysed and properly converted into knowledge.

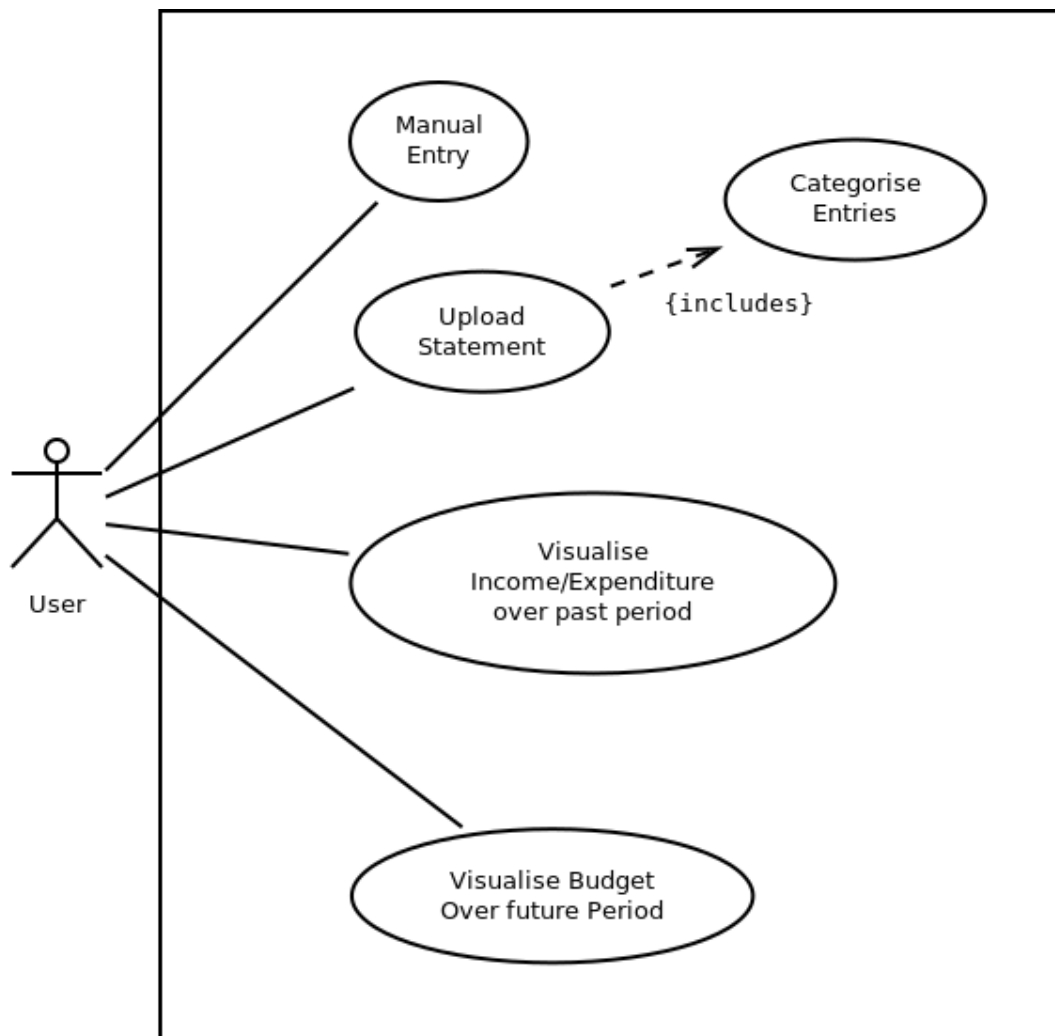

It seems fair to infer that nowadays most of a user’s financial transactions currently happen in ways that can be listed electronically (usually via their bank or credit card statements) – a study by Payments UK (2017), for example, indicates that there has been a rise in debit card payments over the past few years, and that the volumes of this type of transaction is likely to be higher than that of cash payments by the year 2021. Therefore, an assumption has been made that the users will require means of uploading a list of their financial transactions into the system, and this has been identified as a functional requirement.

The system created for this project intends to do just this. Its main feature, however, will be a feature to allow the user to categorise expenditure based on patterns in the entries’ description. However, in order not to restrict the system to the uploading of transactions via bank or credit card statements only, it must also be possible for a user to create entries manually.

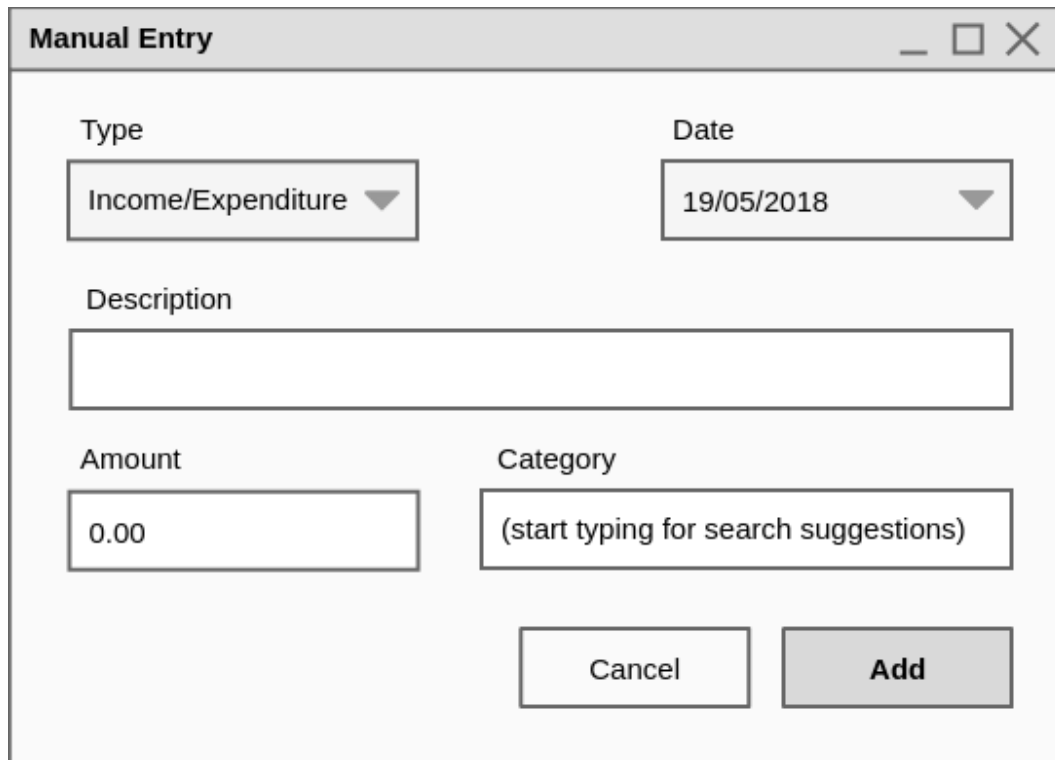

There must also be a feature to allow the user to view summaries of the income and expenditure over a period of time, as well as one to forecast budgets for future periods of time based on the analysed “financial behaviour”.

4.1.1 Requirements Model

Use case diagrams are UML constructs which were developed by Jacobson et al. (1992, cited Bennett et al., 2010, p. 154). The use case diagram below is used to illustrate the functional requirements listed in 4.1:

The wireframe below was created to better illustrate the *Manual Entry* requirement:

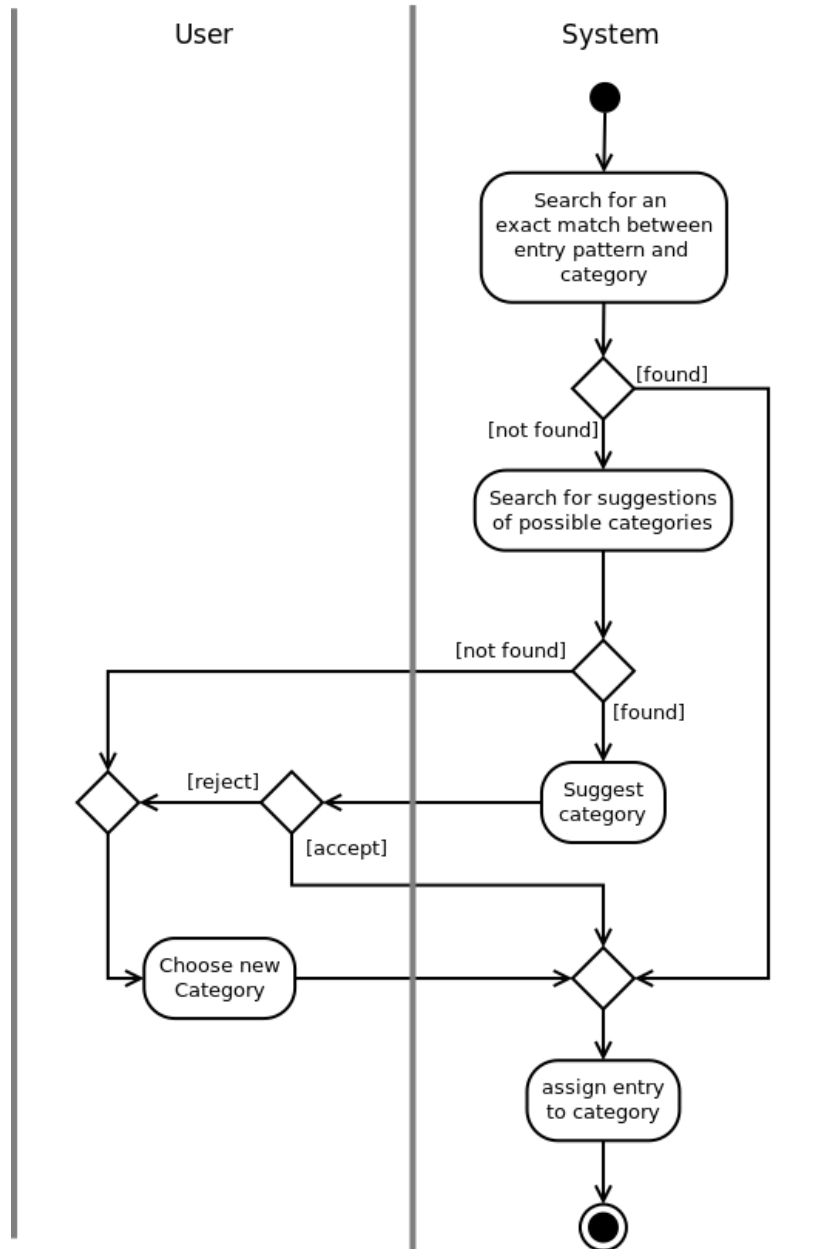

The image shows a 'Manual Entry' dialog box with a title bar containing standard window controls. The form inside has several fields: 'Type' is a dropdown menu showing 'Income/Expenditure'; 'Date' is a date picker showing '19/05/2018'; 'Description' is a large text input field; 'Amount' is a text input field showing '0.00'; and 'Category' is a text input field with placeholder text '(start typing for search suggestions)'. At the bottom right, there are two buttons: 'Cancel' and 'Add'.

Type	Date	Description	Amount	Category
Income/Expenditure ▼	19/05/2018 ▼		0.00	(start typing for search suggestions)

Buttons: Cancel, Add

Also, in order to better understand the relationship between *Upload Statement* and *Categorise Entries*, the activity diagram below was developed:

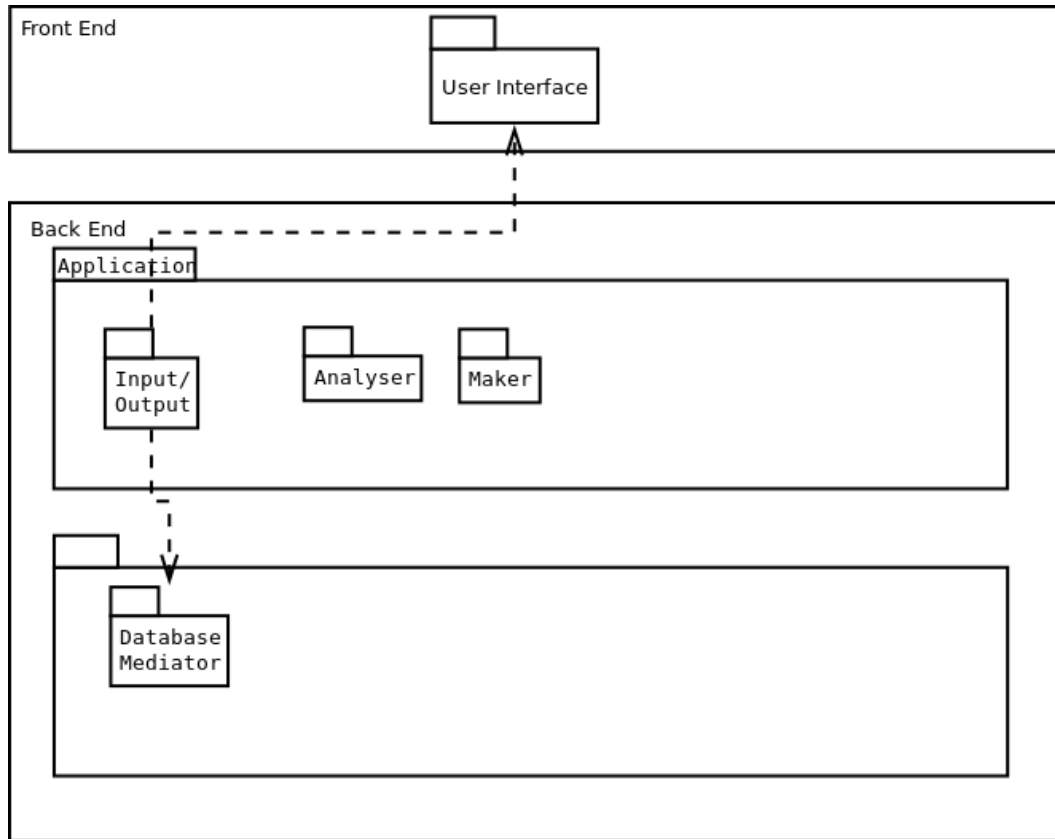

4.2 Non-Functional Requirements

Use cases and use case diagrams are an appropriate tool to document functional requirements, but not non-functional ones (Jacobson et al., 1999, cited Bennett et al., 2010, p. 153). Therefore, a separate list has been kept in order to document the non-functional requirements, where they exist.

4.3 Package Diagram

The diagram below provides a general idea of what the system should look like at a high level:

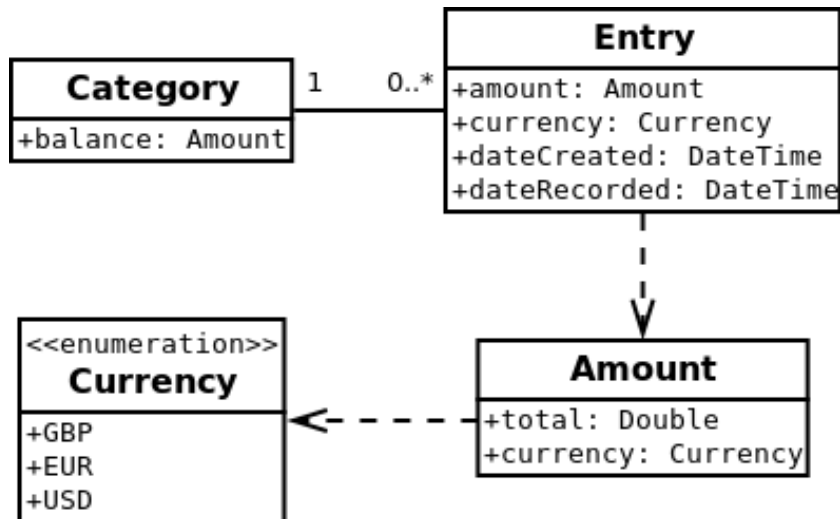

5 Analysis and Design

Seeing that this is a system dealing with finance, it would make sense to treat the categories as if they were the accounts. And, in order to make sure to imbue this system with knowledge acquired by more experienced programmers, it makes sense to make use of patterns.

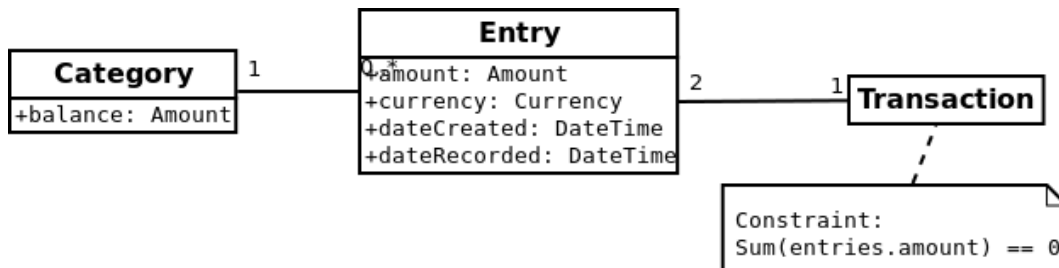

It is also useful at this point to make a distinction between the types of classes being modelled. The first kind are the classes which will model the interaction between the system and its actors – these will be called *boundary classes*. The other kind are those classes which will model information and/or behaviour or some concept or phenomenon – these will be called *entity classes* (Jacobson et al., 1999, cited Bennett et al., 2010, pp. 198-199).

The first analysis patterns which seem appropriate are the *Account* pattern, used to create the *Category* entity class, and the *Quantity* pattern for the *Amount* entity class (Fowler, 1997, Sections 6.1 & 3.1):

As implied by the diagram above, the *Category* class will be associated with instances of the *Entry* class, and will keep track of the balance made up of the sum of *Amount*'s of each entry. This is done so that the only way to change the total of a category is by adding positive or negative entries to it – for example, to indicate a credit to a category, a negative entry can be added to it.

The next step is to provide a way for these entries to be added to categories. For this to happen, there needs to be a constraint in to ensure that double entry happens every time a change needs to be made to a category. One of the ways to achieve this is to apply the *Transaction* pattern (Fowler, 1997, Section 6.2):

6 Reflections

6.1 Expert Systems

Originally, the author did not know about expert systems when the idea for this project was conceived. However, during the literature search and review, the idea for these systems was found, and many of the patterns of what an expert system does and what this system is supposed to do were identified to be similar. This led to the conclusion that the project has the potential to become an expert system, even if just with a budgeting tool. The expert knowledge being provided by it for its first iteration includes:

- Double entry bookkeeping;
- Budgeting by category.

It achieves the above by separating the inference engine, which is the tool responsible for knowing how to apply double entry to transactions, from its knowledge base which is the information input by the user – for example, if the user tells the system a manual entry is income, the system will know to debit the cash book, and credit the category in question.

Brown et al. (1990) declare that the heuristics used by a financial planning system can be interpreted as a “rule of thumb” to be applied to a problem which will normally result in a correct solution for it. In the same article it is also stated that “an expert system is most commonly and most effectively used as an advisor to a human decision maker”. If this is considered as the measure by which to classify an expert system, then the budgeting tool alone would place this system into it.

6.2 Use Case Templates

Originally, no template was used to document the use cases. The intention was to provide better ones at a later iteration, perhaps by researching the ones mentioned by Bennett et al. (2010, p. 157), but unfortunately there was not enough time, so the little there was had to be dedicated to the software itself.
